AMENDMENTS TO THE SPECIFICATION

Please replace the abstract with the following amended abstract:

-- A circuit that permits a processor in a microcontroller too to adjust its clock

speed on the fly. A processor receives a current clock signal and a phased current

clock signal from a speed selection switch. A new speed selection switch provides

a new clock signal and a phased new clock signal for comparison with the current

clock signals. When the states of the current and new clocks appropriately align

after issuance of a control signal from the processor, the new speed is switched

into the current speed switch to permit the clock speed to change without producing

spurious signals that can cause unpredictable action in the processor. This

advantageously allows the microcontroller to adjust its clock speed under program

control. --
